

Summary

The analysis showed that features such as area, number of bathrooms, air conditioning, and preferred location had the strongest influence on house prices. Among the two models tested, Linear Regression performed slightly better than Random Forest, achieving a lower MAE (970,043), lower RMSE (1,324,507), and a higher R^2 score (0.273). This means the model was able to explain about 27% of the variation in house prices, indicating moderate predictive performance. One surprising finding was that amenities such as air conditioning and location preferences significantly affected house prices in addition to the size of the property. The distribution of house prices was also somewhat skewed, with a few high-priced properties influencing the overall range. Based on these findings, real estate businesses should focus on promoting properties with larger areas, modern amenities, and desirable locations, as these factors have the greatest impact on market value.
